Lipids and Heart Health: Know Your Numbers

Lipids: What are they?

- Cholesterol
 - Cholesterol is a waxy, fat-like substance that is found in all the cells in your body, even your brain. Your body needs some cholesterol to make hormones, vitamin D, and to help you digest foods. Your body makes some cholesterol, but it is also found in foods from animal sources, such as egg yolks, meat, and cheese.
 - If you have too much cholesterol in your blood it can combine with other substances in the blood to form plaque. Build-up of plaque in blood vessels is known as atherosclerosis.
- Triglycerides
 - Triglycerides are the storage form of fat in the blood. Having high levels can make your blood thick and milky. This can increase your risk of heart disease.
 - High levels can be caused by eating extra calories or carbohydrates (sugars). Levels may also be high if you smoke, are overweight, use excessive alcohol or take certain medicines.
 - Poorly controlled diabetes, liver or kidney diseases, thyroid diseases and genetics can also cause high levels.

• HDL (High-Density Lipoproteins)

• HDL is sometimes called **"good"** cholesterol because it carries cholesterol from other parts of your body back to your liver. Your liver then removes the cholesterol from your body.

• LDL (Low-Density Lipoproteins)

 LDL is a lipoprotein that circulates in the blood, moving cholesterol around the body to where it is needed for cell repair. LDL is sometimes called "bad" cholesterol because a high LDL level can lead to the buildup of plaque in your arteries.
